## Solution

## a. Frequency Distribution Table

Choosing class interval of size 10 from $80-89$ and ends at $200-209$, we compute the frequency distribution table as follows:
Frequency Distribution Table

| Class Interval (x) (in Dollars) | frequency (f) | Mid-Class Interval | $\mathrm{x}-\mathrm{A}$ | $\mathrm{MD}=\mathrm{f}(\mathrm{x}-$ - |
| :---: | :---: | :---: | :---: | :---: |
| $80-89$ | 1 | 84.5 | -60 | -60 |
| $90-99$ | 3 | 94.5 | -50 | -150 |
| $100-109$ | 3 | 104.5 | -40 | -120 |
| $111-119$ | 4 | 114.5 | -30 | -120 |
| $120-129$ | 4 | 124.5 | -20 | -80 |
| $130-139$ | 5 | 134.5 | -10 | -50 |
| $140-149$ | 7 | 144.5 | 0 | 0 |
| $150-159$ | 6 | 154.5 | 10 | 60 |
| $160-169$ | 5 | 164.5 | 20 | 100 |
| $170-179$ | 4 | 174.5 | 30 | 120 |
| $180-189$ | 3 | 184.5 | 40 | 120 |
| $190-199$ | 2 | 194.5 | 50 | 100 |
| $200-209$ | 3 | 204.5 | 60 | 180 |
|  | 50 |  |  | 100 |

b. Arithmetic Mean (Using the method of assumed Mean)

From the the table, we choose an Assumed mean $\mathbf{A}=144.5$ and obtained the deviation from assumed mean the fourth column i.e $x-\mathbf{A}$, the product of the mean deviation and the frequency $f$, is calculated in the last column which is $f(x-\mathbf{A})$.
we can now compute the Mean as follows
Assumed mean A =144.5
Mean deviation

$$
\mathbf{M D}=\frac{\sum f(x-\mathbf{A})}{\sum f}=\frac{100}{50}=2
$$

Then the real Mean $\bar{x}$ can be computed as

$$
\bar{x}=\mathbf{A}+\mathbf{M D}=144.5+2=146.5
$$

Therefore the mean is 146.5 .
